

Realistic Intersection Generation: Using Clothoid Spirals

Will Bloomfield

July 2024

1 Introduction

We present a method for procedurally generating road intersection layouts, including realistic geometric details and lane configurations. This approach emphasizes the use of Clothoid Spirals in road generation.

2 Methods for Intersection Generation

Generating road intersections requires a two-phase process. Phase 1 involves generating incident roads using helper roads created with Clothoid Curves. In Phase 2, we create connection roads based on a set of link configuration rules.

2.1 Phase 1: Incident Road Generation

In Phase 1 [4.1], we generate the headings and starting points for all the incident roads. To achieve this, we use helper roads to place the incident roads one by one. Additionally, we determine the number of lanes for each incident road and can insert partitions between the lanes if desired.

An outline of the steps in Phase 1:

1. Create the initial incident road [4.2].
2. Generate a helper road starting from the initial incident road [4.3].
3. Check if the end point of the helper road is in the vicinity of the placed incident roads. If the distance is too close, repeat step 2.
4. If the end point passes the check in step 3, place the incident road at the end of the helper path using the coordinates and heading from the helper path.
5. Repeat steps 2, 3, and 4 for the desired number of incident roads, changing the starting point of the helper road in step 2 to the new incident road.

Figure 1: Outline of Steps in Phase 1

2.1.1 The Helper Path: Clothoid Curve Fitting [4.3]

To construct our helper roads, we will use the simplest form of the clothoid curve, as described below. We only require the initial coordinates, heading, desired initial curvature, and the curvature rate of change.

Definition 1 (Clothoid Curve).

$$x(0) = x_0, \quad y(0) = y_0, \quad \theta(0) = \theta_0$$

$$\begin{aligned} \frac{dx}{ds} &= \cos(\theta), \\ \frac{dy}{ds} &= \sin(\theta), \\ \frac{d\theta}{ds} &= \kappa_0 + \kappa_1 s. \end{aligned}$$

where κ_0 is the initial curvature, κ_1 is the curvature rate of change and, s is the arc length. Given our Initial conditions (x_0, y_0) and the heading θ_0 taken from our Incident Road.

Remark 1. This set of differential equations describes the motion of a particle in a plane where θ is the angle with the horizontal axis and κ_0 and κ_1 are constants related to the curvature of the path.

Remark 2. θ must be in the range $[-\pi, \pi]$

2.1.2 Adding Lanes

Given a lane width, one can easily add lanes by keeping the existing curves as the midpoints. Using the heading, we find the two perpendicular angles and then transform the initial point half of the lane width in the new direction [4.1].

To enhance realism, we allow for random lane widths for each incident road. Since most lanes do not have exactly the same width, our lane widths are generated to simulate this variability.

2.1.3 Incident Road Variations

Multiple lanes

For multiple lanes, we randomly generate an integer in the range of 1 to 3, which corresponds to the number of lanes on the incident road. By keeping the initial lane central, we first add one lane to the left and then a second lane to the right. The code can be found here [4.2].

Partitions

Similarly, we randomly decide whether an incident road will have partitions. This decision applies to all lanes on the given incident road. The code for this is also found in the Initial Incident Road Generation [4.2].

Figure 2: Incident Roads with multiple lanes and partitions

2.2 Phase 2: Generating Connection Roads

With the Incident Roads Placed we move on to Connections Roads. Each Incident Road has an initial position (x_0, y_0) , Angle in v_1 and Angle out v_1 . We will use a more generalised clothoid curve to connect the incident roads. We will also confront the lane configuration and the Boundary conditions of the Junction.

An outline of the steps in Phase 2:

1. For each incident road, calculate the lane configuration for the remaining incident roads [4.4].
2. Calculate the clothoid curve for each lane in the configuration [4.5].
3. Repeat steps 1 and 2 for all incident roads.
4. Create the boundaries for the junction [4.6].

2.2.1 Connection Road: Clothoid Fitting [4.5]

Definition 2 (Generalised Clothoid Curve). *The general parametric form of a Clothoid spiral curve is the following*

$$\begin{aligned} x(s) &= x_0 + \int_0^s \cos\left(\frac{1}{2}\kappa_1 + \kappa_0 + v_0\right) d\tau, \\ y(s) &= y_0 + \int_0^s \sin\left(\frac{1}{2}\kappa_1 + \kappa_0 + v_0\right) d\tau \end{aligned} \quad (1)$$

where s is the arc length, $\kappa_1 t + \kappa_0$ is the linearly varying curvature, (x_0, y_0) is the starting points and v_0 initial angle.

Problem 1. Given two points (x_0, y_0) , (x_1, y_1) and two angles v_0 (angle out of (x_0, y_0)), v_1 (angle in for (x_1, y_1)), find a clothoid segment for the form (1) which satisfies :

$$\begin{aligned} x(0) &= x_0, \quad y(0) = y_0, \quad \arctan\left(\frac{y'(0)}{x'(0)}\right) = v_0, \\ x(L) &= x_1, \quad y(L) = y_1, \quad \arctan\left(\frac{y'(L)}{x'(L)}\right) = v_1 \end{aligned} \quad (2)$$

Solution 1. Solution of Problem 1 is a zero of the following nonlinear system involving the unknowns L , κ_0 , κ_1 :

$$F(L, \kappa_0, \kappa_1) = \begin{pmatrix} x_1 - x_0 - \int_0^L \cos\left(\frac{1}{2}\kappa_1 s^2 + \kappa_0 + v_0\right) ds \\ y_1 - y_0 - \int_0^L \sin\left(\frac{1}{2}\kappa_1 s^2 + \kappa_0 + v_0\right) ds \\ v_1 - \left(\frac{1}{2}\kappa_1 L^2 + \kappa_0 L + v_0\right) \end{pmatrix} \quad (3)$$

So we need to find the values such that $F(L, \kappa_0, \kappa_1) = 0$. We will now reformulate the system to reduce the number of unknowns, to make solving the system less computationally heavy.

Reformulation of the Problem

We can reduce the Dimension of the nonlinear system (3) by introducing the parametrization $s = \tau L$, $L \in \mathbb{R}$.

$$F\left(L, \frac{B}{L}, \frac{2A}{L^2}\right) = \begin{pmatrix} \Delta x - L \int_0^1 \cos(A\tau^2 + B\tau + v_0) d\tau \\ \Delta y - L \int_0^1 \sin(A\tau^2 + B\tau + v_0) d\tau \\ v_1 - (A + B + v_0) \end{pmatrix} \quad (4)$$

where $A = \frac{1}{2}\kappa_1 L^2$, $B = L\kappa_0$, $\Delta x = x_1 - x_0$, $\Delta y = y_1 - y_0$.

Notice the third equation (4) is linear, so Consider

$$B = \Delta v - A, \quad \Delta v = v_1 - v_0 \quad (5)$$

then the system can be reduces to a system of 2 equations with 2 unknowns, A and L.

$$G(L, A) = \begin{pmatrix} \Delta x - L \int_0^1 \cos(\cos(A\tau^2 + (\Delta v - A)\tau + v_0) d\tau \\ \Delta y - L \int_0^1 \sin(\cos(A\tau^2 + (\Delta v - A)\tau + v_0) d\tau \end{pmatrix} \quad (6)$$

For further simplification we can use polar coordinates for $\Delta x, \Delta y$

$$\Delta x = r \cos \phi, \quad \Delta y = r \sin \phi, \quad r = \sqrt{(\Delta x)^2 + (\Delta y)^2} \quad (7)$$

from (7) and $L > 0$ we define two new nonlinear functions $f(L, A)$ and $g(A)$:

$$f(L, A) = G(L, A) \cdot \begin{pmatrix} \cos \phi \\ \sin \phi \end{pmatrix}, \quad g(A) = \frac{1}{L} G(L, A) \cdot \begin{pmatrix} \sin \phi \\ -\cos \phi \end{pmatrix}. \quad (8)$$

Using the identity $\sin(\alpha - \beta) = \sin \alpha \cos \beta - \cos \alpha \sin \beta$, we can rewrite $g(A)$:

$$g(A) = \int_0^1 \sin(A\tau^2 + (\Delta v - A)\tau + \Delta\phi) d\tau \quad (9)$$

where $\Delta\phi = v_0 - \phi$

Similar one can use the identity $\cos(\alpha - \beta) = \cos \alpha \cos \beta + \sin \alpha \sin \beta$ to reduce $f(L, A)$:

$$f(L, A) = r - Lh(A), \quad (10)$$

$$h(A) = \int_0^1 \cos(A\tau^2 + (\Delta v - A)\tau + \Delta\phi) d\tau \quad (11)$$

Lemma 1.

$$g(A) = 0, \rightarrow h(A) \neq 0. \quad (12)$$

Proof. Proof can be found in "fast and accurate Clothoid fitting" \square

Lemma 2. The solutions of the nonlinear system (6) are given by

$$L = \frac{r}{h(A)}, \quad \kappa_0 = \frac{\Delta v - A}{L}, \quad \kappa_1 = \frac{2A}{L^2} \quad (13)$$

where A is the root of $g(A)$ defined in (8) and $h(a)$ is defined in (11)

Proof. Let L, A satisfy (8) and (13). Then $f(L, A) = 0$ and hence $G(L, A) = 0$ from lemma 1 when $g(A) = 0$ then $h(A) \neq 0$ and thus L is well defined. \square

Hence our interpolation problem is reduced to a single equation that can be solved numerically with the Newton Raphson Method.

2.2.2 Connection Road: Clothoid Fitting Algorithm [4.5]

Algorithm 1 Clothoid Curve Generation

Require: $x_0, y_0, x_1, y_1, v_0, v_1$

Normalize v_0, v_1

Compute $\Delta x, \Delta y, \Delta v$

Compute $\phi = \arctan\left(\frac{\Delta y}{\Delta x}\right)$, r and $\Delta\phi$

Normalize $\Delta v, \Delta\phi$

Define $g(A)$

Define $dG(A)$

Solve $g(A) = 0$ for A using the Newton-Raphson method

Define $h(A)$

Compute L, κ_0, κ_1

Compute x_values and y_values using Definition 2 (1)

Return x_values, y_values

Algorithm 2 Normalize(θ)

while $\theta > +\pi$ do $\theta - 2\pi$

while $\theta < -\pi$ do $\theta + 2\pi$

return θ ;

2.2.3 Lane configuration 4.4

An intersection does not require every lane to connect. In our model, the lanes have no specific directions, and each incident road has a maximum of 3 lanes. Therefore, we manually coded the logic for which lanes connect to which. Lane configuration can be a complex problem that might warrant a separate paper dedicated to the general issue, so we did not explore it further.

We can see our basic lane configuration below:

Figure 3: Junctions with Connection Roads Showing

2.2.4 Boundary Generation [4.6]

We also generate the boundary curves for the junctions. This involves calculating clothoid curves in a clockwise direction, starting from the far-left lane of one incident road and connecting to the far-right lane of the adjacent incident road. This process is repeated to define the complete boundary of the junction.

When partitions are present, we use clothoid curves to create smooth, curved boundaries. Below, you can see examples of junctions where only the boundary curves have been generated.

Figure 4: Junctions with Boundaries Showing

2.3 Adding Static Vehicles

As an additional feature of the project, we introduced static vehicles on the connecting lanes. To ensure realistic traffic behavior in the absence of traffic lights, vehicles are generated only on one selected incident road, limiting their movement to this road. Vehicles are randomly placed along the path while maintaining a minimum distance between them to prevent overlap.

Furthermore, each vehicle's orientation is aligned with the heading of the connecting path, ensuring that the vehicles face the correct direction relative to their position on the road.

Figure 5: Junctions with Boundaries Showing

3 Conclusion and Future Work

This project effectively demonstrates a method for procedurally generating road intersections with a focus on realism and functionality. By employing a two-phase approach, we have successfully integrated realistic geometric details and lane configurations into the intersection design.

In Phase 1, the initial incident roads are placed using helper roads defined by clothoid curves. This allows for random, yet realistic lane placement and configuration, including random lane widths and optional partitions, enhancing the realism of the road network. In Phase 2, we ensure that connection roads align accurately with the incident roads by calculating lane configurations and generating boundary curves. The use of clothoid curves to define junction boundaries provides smooth transitions between lanes, even in the presence of partitions. Additionally, the inclusion of static vehicles on the connecting lanes adds a layer of realism to traffic behavior. By randomly placing vehicles and aligning their orientation with the heading of the connecting paths, the model simulates a more lifelike traffic environment.

Overall, the project addresses the complexities of road intersection design and offers a robust framework for generating realistic and functional road networks. The approach can serve as a foundation for further exploration into more complex traffic simulations and road design challenges.

For future work, developing a more robust lane configuration function would be beneficial, especially for handling scenarios with more than three lanes, such as four lanes. One initial idea is to start with our existing framework for two lanes and then divide them to create four lanes. Additionally, the current vehicle placement function is relatively basic and could be enhanced, particularly by improving the proximity conditions between vehicles. Currently, many configurations are randomized by design. Adding more control over how junctions are generated could also be advantageous for achieving more precise and realistic results.

4
5      Parameters:
6      Incident_roads (list): List of roads where each road contains data about its segments and
7          characteristics.
8      Incident_road_index (int): Index of the road from which to generate paths.
9
10     Returns:
11     list: List of generated connection roads.
